2015 PROGRESS REPORT

for the Hillsborough River Basin Management Action Plan

prepared by the
Division of Environmental Assessment and Restoration
Water Quality Restoration Program
Florida Department of Environmental Protection

with participation from the
Hillsborough River Basin Stakeholders

March 2016

2600 Blair Stone Rd.
Tallahassee, FL 32399-2400
ACKNOWLEDGMENTS

This 2015 Progress Report for the Hillsborough River Basin Management Action Plan was prepared as part of a statewide watershed management approach to restore and protect Florida's water quality. It was prepared by the Florida Department of Environmental Protection with participation from the Hillsborough River Basin stakeholders.

Section 1: INTRODUCTION

1.1 PURPOSE OF THE REPORT
This is the sixth Annual Progress Report for the Hillsborough River Basin Management Action Plan (BMAP). Section 2 describes the water quality monitoring that occurred during the reporting period, and Section 3 discusses the efforts in the upcoming reporting period. Project and activity updates implemented by stakeholders during the reporting period (November 1, 2014, through October 31, 2015) are not included in this report, since they were recently included in the Phase 2 BMAP update document.

1.2 TOTAL MAXIMUM DAILY LOADS (TMDLs) FOR THE HILLSBOROUGH RIVER BASIN
Within portions of the Hillsborough River Basin, fecal coliform bacteria were identified as the primary pollutant causing impairment. The BMAP boundaries outline the geographic areas this plan covers (see Figure 1). In 2003, the Florida Department of Environmental Protection (DEP) adopted TMDLs for six of the verified impaired waterbodies in the Hillsborough River Basin. DEP adopted the Hillsborough River BMAP in October 2009 to implement the coliform TMDLs in the watershed.

The second iteration (five-year period) of the BMAP went into effect in 2015. Through the original 2009 BMAP and the Phase 2 update document, DEP will track ongoing and additional efforts to help assess current and future strategies.

The fecal coliform TMDLs that define the required fecal coliform reductions needed for each segment or tributary with a waterbody identification (WBID) number are available online.
Figure 1: Hillsborough River BMAP areas
1.3 **RESponsible Parties and Key Stakeholders**

The following organizations and entities are key stakeholders in the Hillsborough River BMAP:

- Agriculture.
- City of Plant City.
- City of Tampa.
- City of Temple Terrace.
- Environmental Protection Commission of Hillsborough County (EPCHC).
- Florida Department of Health in Hillsborough County.
- Hillsborough County.
- Pasco County.
- Polk County.
- Florida Department of Agriculture and Consumer Services (FDACS).
- Florida Department of Environmental Protection (DEP).
- Florida Department of Transportation.
- Southwest Florida Water Management District.
- Tampa Bay Estuary Program.
- University of Florida–Institute of Food and Agricultural Sciences (UF–IFAS).
- University of South Florida.

1.4 **Fecal Coliform Reductions Since BMAP Adoption**

DEP determines progress towards meeting the fecal coliform criterion for the 6 verified impaired waterbodies by assessing the frequency with which the criterion for each tributary is exceeded. This approach mirrors the Impaired Surface Waters Rule (IWR) methodology in Chapter 62-303, Florida Administrative Code (F.A.C.). The IWR criterion during 2015 was set so that if more than 10% of the data exceeded 400 colony-forming units per 100 milliliters (cfu/100mL) during each verified period, the water is verified as impaired.
Column 5 in Table 1 shows the minimum number of exceedances needed to place a waterbody on the Verified List with at least a 90% confidence level. The minimum number of exceedances is compared with the number of exceedances to determine if the IWR criterion is being met. The last column in Table 1 shows each WBID's percent exceedance, which is based on the number of exceedances (Column 4) relative to the total number of data points (Column 3) for the most recent 7.5-year dataset. The tributaries are listed in order of lowest to highest percent exceedance.

</table>

Table 2 shows the percent exceedance of the IWR data periods analyzed prior to BMAP adoption (Cycle 1 and Cycle 2) and at the time of BMAP adoption (Cycle 3). Each cycle's verified period includes 7.5 years of data. To show current progress, the percent exceedance for the most recent 7.5 years of data was calculated (as described and listed above) for each WBID and included in the last column of Table 2. The current dataset was obtained from the Cycle 3 assessment dataset and the state's Storage and Retrieval (STORET) Database. The data search in STORET was limited to the same set of stations used in the Cycle 3 assessment dataset, and was only searched to obtain more recent data (data outside the IWR Run 50 date range).

A comparison of the data periods shows that the percent exceedance gradually decreased in the Lower Hillsborough River, Baker Creek, New River, and Spartman Branch since the Cycle 2 assessment period. The most recent data period (Column 6) shows a slight decrease in percent exceedance for Flint Creek and a slight increase in percent exceedance for Blackwater Creek.
Pasco County data were not included in the Cycle 3 New River assessment because they were not available in STORET in time for the IWR Run 50 data pull on October 31, 2014. The dataset used to assess the current 7.5-year period includes the Cycle 3 assessment data, supplemental STORET data, and Pasco County data. The Pasco County dataset begins in 2008. The county data that fall within the dates of the Cycle 4 assessment period are likely to be included in the Cycle 4 assessment because the county is now uploading its data to STORET.

Section 2: Water Quality Monitoring and Patterns

2.1 Water Quality Monitoring

The Hillsborough River monitoring plan supports the implementation of the BMAP by providing water quality data and other information that can be used to document status and track trends in fecal coliform levels and other microbial water quality conditions in the six BMAP WBIDs. The information collected through the monitoring plan is used to evaluate progress toward achieving BMAP objectives, to demonstrate progress toward meeting the TMDL, to facilitate comparisons of water quality in the BMAP watersheds before and after the implementation of best management practices (BMPs), and to provide information to help guide the selection of future BMPs.

The BMAP monitoring plan consists of ambient water quality sampling at ten stations. The stations are sampled quarterly, with some sampled more frequently for other programs. The BMAP monitoring stations are monitored by the EPCHC, Polk County, and Pasco County. Hillsborough River BMAP data providers upload their data to STORET regularly, at least twice a year. Appendix A lists the monitoring stations in the BMAP monitoring plan and contains a map of the stations.

2.2 Water Quality Trends

The following data plots depict the fecal coliform data at each BMAP monitoring station in each BMAP tributary and how they compare with the state water quality criterion of 400 cfu/100mL. BMAP progress assessments, as presented in Section 1.4, are based on the number of exceedances relative to the total number of samples in each WBID during a 7.5-year period, based on the IWR assessment methodology.

For determining impairment, the IWR assessments use a larger dataset, obtained by evaluating data from additional monitoring sites in the watershed. This section only includes data from the BMAP monitoring network stations that are a subset of the IWR monitoring network. The BMAP monitoring network station data plots help decision makers gain a basic understanding of water quality in the BMAP watersheds, provide a visual way to detect increases or decreases in the magnitude of the monitoring results, and assist in determining seasonal influences on water quality.

In July 2015, more than 11 inches of rain flooded the western regions of the basin, affecting water quality. Rainfall levels were more than 4 inches over the typical average rainfall for July. Fecal coliform levels that spiked above 400 cfu/100mL in some creeks during the July 2015 sampling events may have
been caused by rainfall washing and suspending bacteria into the water column that usually remains in
the sediments.

2.2.1 Blackwater Creek
As shown in Figure 2, in Blackwater Creek from 2002 to 2015 periodic spikes over the state criterion of
400 cfu/100mL were observed at Station 21FLHILL143, located in the lower portion of the main artery
of Blackwater Creek. This artery experiences frequent flushing and flows continuously most of the year,
while flows slow during the dry season. The frequency of exceedance of the state criterion at Station
21FLPOLKBLACKWATER CR2 remains high. The median value for 2015 at Station 21FLHILL143
was 80 cfu/100mL, while at Station 21FLPOLKBLACKWATER CR2, the median value was 800
cfu/100mL.

Station 21FLPOLKBLACKWATER CR2 is in an upper reach of Blackwater Creek that does not receive
enough rainfall to keep this site flowing year-round. Therefore, in some months the location is not
sampled. However, the sediment in the broad floodplain of this heavily canopied segment of the creek
stays moist most of the year. During rainfall events, disturbances of this moist sediment may, in part,
cause spikes in fecal coliform as natural bacteria from sediment are released into the water column. Polk
County has begun taking *Escherichia coli* (*E. coli*) samples at this station, and county staff have
investigated nearby areas for potential illicit connections to the natural system. No illicit connections
have been found recently.

2.2.2 New River
New River flow is intermittent, and therefore the river is not sampled when it is not flowing. Station
21FLPASC PASCO SITE 15 is north and upstream of the county line between Hillsborough and Pasco
Counties. Pasco and Hillsborough County staff are working collaboratively to determine if there are
sources of bacteria between the two stations that may be elevating the levels at Station 21FLHILL523.
Figure 3 shows the intermittent spikes above the state criterion of 400 cfu/100mL that occurred between
2005 and 2015. The levels of the spikes do not indicate a raw human sewage source, but investigations
will continue to ensure that no illicit connections are contributing to the impairment. The sources are
unknown at this time. As a precautionary effort, FDACS and UF–IFAS are focusing BMP educational
efforts in this area to inform local producers and livestock owners of the bacteria impairment and how
their actions can protect the river's water quality.

Section 3: UPCOMING ACTIVITIES

DEP has updated the current water quality standard for Class III (recreational use) waters from fecal coliform to *E. coli* in freshwater environments and *Enterococci* in marine environments. To transition to the new criterion, the BMAP efforts will continue to implement the fecal coliform TMDLs while integrating sampling for *E. coli* and/or *Enterococci*, so that the waterbodies can be assessed using the new water quality standard during the next assessment cycle. The *E. coli* and/or *Enterococci* data will be used to guide future restoration efforts. In the meantime, high-magnitude fecal coliform exceedances remain a good tool to direct field investigations and management strategies.

Stakeholders will continue the implementation of ongoing maintenance programs and planned projects during the upcoming year. Meanwhile, DEP and stakeholders will work together to continue to identify the sources of fecal indicator bacteria through field investigations and monitoring of source indicator parameters.
